

React Components

1. What are componenets
2. Types of components
3. Similarities and differences
4. Neking of components

1. What are components

- A Component is the core building blocks of a React application.
- It can be considered as independent, reusable pieces.
- It makes the task of building UIs much easier.
- Every component has it's own structure, style and logic for event handling.
- Componentets define its UI in the form of JSX

- There are 2 types of components
 - **Functional Component:**
 - They are simply JavaScript functions
 - This function returns what should be rendered(displayed in the UI)
 - It is stateless component because it does not hold or manage state.
 - **Class Component:**
 - They are written as javascript class
 - It should extend from React.Component
 - It should have render method which returns JSX which is UI of the class component
- When creating a React component, the component's name must start with an upper case letter.

3. Similarities and Differences

- Similarities
 - Both types of components can have props and return HTML as component's UI
- Differences

Functional Component	Class Component
Implemented as javascript function	Implemented as javascript class
No render method	Must have render method
Stateless	Stateful
Lifecycle methods can not be used	Lifecycle methods can be used

4. Nesting of components

- One component can use another component in its UI
- There is no limitation as such for this levels of nesting
