

React Component Styling

- Inline styles can be added to the react element by writing as attributes.
- Inline style attribute must be a JavaScript object.
- Example
`<h1 style={{color: "red"}}>Hello Style!</h1>`
- React JSX uses {} for writing expression and JS object itself has to be written in {}.
- Properties with hyphen separated names, must be written with camel case syntax
- A separate object can be created with styling information which can be reused

- This involves the use of external CSS stylesheets that can be imported into your React components.
- External CSS file is created by defining style rules as per the requirement.
- Once imported, react component elements will acquire styles defined in external CSS
- Even classnames in the external CSS can be used for styling the react component

- CSS Modules are convenient for components that are placed in separate files.
- Create the CSS module with the .module.css extension, example: mystyle.module.css having style rules defined.
- Import styles from this module like:
`import styles from './mystyle.module.css';`
- Apply style to react component like
`<h1 className={styles.bigblue}>Hello!</h1>;`

- It is one of the very frequently used frameworks for styling
- Steps to be followed:
 - Install Bootstrap in a React app:
Can be done using `npm install bootstrap`
 - Adding Bootstrap files in a React App
In `index.js`, import bootstrap css and js files
 - Testing bootstrap installation
Use bootstrap classes for styling the react elements
